(54) Title: LOW PROFILE, PIVOTAL CONNECTION INFUSION ASSEMBLY

(57) Abstract: This invention relates to therapeutic infusion assemblies, more specifically a device for the subcutaneous delivery of a fluid from a remote source. Applicant provides a base assembly which has a fluid channel therein and a cannula extending vertically downward from a flat bottom. A fluid connector member which receives a fluid bearing line from the remote fluid source and the fluid connector member pivotably and removably connects to the base member. The manner of connection is "hinged" allowing the fluid connector to move from a non-use position by rotation downward to a used position. In the use position a fluid channel in the fluid connector will connect with a fluid channel in the base to provide fluid to the cannula and to the patient.

WO 03/075980 A2

LOW PROFILE, PIVOTAL CONNECTION INFUSION ASSEMBLY

1 This application claims priority to U.S. Provisional Patent Applications Serial
2 Nos. 60/362,593, filed March 8, 2002; 60/388,926, filed June 14, 2002; and 60/435,143,
3 filed December 20, 2002; all of which are incorporated herein for all purposes.

4

5 BACKGROUND OF THE INVENTION

6 This invention relates to therapeutic infusion assemblies and, more specifically,
7 to a device for subcutaneous delivery of a fluid to a patient. The present invention
8 provides an infusion set having a pivoting fluid connector and a base assembly having a
9 base unit and a molded septum. The invention is easy to manufacture and assemble and
10 is simple to use.

11 Prior art infusion sets provide a number of ways for engaging a fluid connector
12 to a base. The base typically has a vertical cannula depending downward from a flat
13 bottom. The fluid connector typically has a fluid line carrying fluid from a remote
14 reservoir to the base. The fluid connector is typically adapted to being removed from
15 the base of the infusion assembly so that one may have freedom of movement, by
16 disconnecting the fluid connector and leaving only the base attached to the patient.

17 Many prior art infusion assemblies use septums, piercable with a needle. The
18 septums perform one or more functions. For example, prior art infusion assemblies use
19 a septum with a hollow needle for repeatedly piercing the septum. The piercing needle
20 is normally a part of the fluid connector and adapted for delivery of a fluid from a
21 remote reservoir through the needle to the patient. The base assembly usually includes
22 a cannula which will receive the fluid and introduce it into the patient. The prior art

1 shows that the septums also receive an insertion needle for initially affixing the infusion
2 assembly to the patient.

3 One of the typical functions of a septum is to releasably seal a chamber, usually
4 within a base assembly, when a needle is urged through it and subsequently removed.
5 A septum may be disk shaped or tabular shaped and defines a wall that seals or
6 separates two cavities. It is typically soft enough to be pierced repeatedly by a needle
7 and reform its shape when the needle is removed. It may or may not include a self
8 sealing slit. Further, the walls of the septum are typically under some compression such
9 that when a needle is removed, resiliency will allow the septum to reform its integrity
10 and maintain the seal between two cavities.

11 In a preferred embodiment of the present invention, a base assembly includes a
12 septum. The base assembly has a cannula, and the cannula has a lumen axis. A septum
13 in the base assembly aligned with the lumen axis is provided so that the insertion needle
14 may be used to pierce the septum, passing through the cannula and setting the infusion
15 assembly onto the patient. In the septum, vertical and horizontal channels are typically
16 provided. The vertical channel is generally vertical with respect to the flat bottom of
17 the base and the horizontal channel is horizontal with respect to the base. The vertical
18 and horizontal channels are in fluid communication. The junction of the two channels
19 is below that section of the septum intended for receiving the insertion needle.

20 Also provided is a novel fluid connector for pivotal engagement with the base
21 assembly. The fluid connector has a fluid channel therein. The base assembly and the
22 fluid connector are adapted such that the fluid connector may move from a first (non-

1 operational) position to a second position (operational). The operational position
2 provides fluid engagement with the horizontal channel of the base assembly to the fluid
3 channel in the fluid connector. That is, the base assembly and the fluid connector are
4 designed such that they pivotally engage to move the fluid connector from an
5 operational position wherein the fluid channel therein is in axial alignment and in fluid
6 communication with the horizontal channel of the base assembly (sometimes also
7 referred to as a “use” or “down” position) to a non-operational position wherein the
8 fluid channel of the fluid connector is parallel to the vertical channel of the base
9 assembly and perpendicular to the horizontal channel of the base assembly (sometimes
10 also referred to as the “nonuse” or “up” position).

11 Another feature of the present invention is a hinged leg having a foot section
12 extending perpendicularly therefrom. The hinged leg may be part of the base assembly.
13 In a first position biased upwardly and adjacent a fluid entry portal in the septum, the
14 foot of the hinged leg blocks the entry portal to prevent material from entry or exit from
15 the portal. In this blocking position, the fluid connector is not engaged with the septum
16 and fluid is not communicating through the base assembly into the patient. When the
17 fluid connector is engaged with the base assembly in operational positions, the hinged
18 leg is urged downwardly and the foot is no longer blocking the entry portal. When the
19 fluid connector is aligned in this arrangement fluid may be delivered through the
20 infusion assembly and into the patient.

21

22

SUMMARY OF THE INVENTION

1 An infusion assembly having, typically, three main parts is disclosed. The first
2 part is a single piece septum having a first channel and a second channel. The first
3 channel is open at a first end thereof and intersects the second channel. The second
4 channel is generally perpendicular to the first channel and open at the bottom end
5 thereof.

6 A second main part of the infusion assembly is a base unit. The base unit has a
7 flat bottom plate adapted to either lay adjacent the skin of the patient or be attached to a
8 flexible adhesive member which, in turn, will adhesively and removably attach to the
9 skin of the patient. The base unit further includes a soft rubber or plastic cannula which
10 depends generally perpendicularly downwardly from the under surface of the bottom
11 plate for insertion beneath the skin of the patient. The base unit also may include a
12 shoulder and a pair of spaced apart, vertically oriented sidewalls which will function to
13 guide a fluid connector from a first up or elevated position to a second down position.
14 The base unit may also further include a biased or hinged leg member having a
15 proximal end which is pivotally attached to the bottom plate and a distal or removed
16 end having a perpendicularly extending foot which is normally biased upwardly above
17 the bottom plate. The leg member is capable of pivotal movement between an elevated
18 position where the distal end of the leg (the foot) occludes or blocks an entry portal
19 defined by the first channel opening of the septum. The leg member is further capable
20 of movement to a depressed position where the distal end is below or beneath the first
21 channel opening. In the depressed position the leg member may be substantially flush
22 with an upper surface of the bottom plate of the base unit. The base unit further

1 includes means, such as arms, for releasably maintaining the fluid connector in a down
2 position. The base is further dimensioned for receiving and positioning the septum such
3 that the second channel of the septum is aligned with the cannula.

4 As will be understood further below, the septum and the base unit form the base
5 assembly. While this disclosure discusses the base unit and septum as separate parts, it
6 should be further understood that they may be molded in a unitary fashion or molded
7 separately.

8 The third major element of the infusion assembly is a fluid connector having a
9 near end, a bottom surface, a vertical wall and a lip at the removed end thereof. The lip
10 is provided for pivotal engagement with a shoulder of a fluid connector engaging
11 member of the base unit. The fluid connector includes walls adapted to engage the
12 spaced apart sidewalls of the base unit such that the fluid connector is capable of
13 pivoting from an up position to a down position. The fluid connector also has a fluid
14 delivery channel therein which will lay adjacent the first channel opening of the septum
15 when the fluid connector is in the down or operational position.

16 In the second preferred embodiment provision is made for legs, protruding
17 vertically from a base unit acting to hold and push forward for good seating, the base
18 unit against the septum. The second embodiment may feature a single durometer one
19 piece septum that is designed to "pop" into the base unit for easy assembly. The septum
20 typically includes a raised "nose" portion to assist in joining the septum to the fluid
21 connector for a seal type fit between the septum and the fluid connector. Applicants
22 also provide a relatively smooth top surface to the fluid connector.

1 An alternate preferred embodiment of the present invention provides a base unit
2 formed to provide both vertical and horizontal channels, for engagement with the fluid
3 connector wherein the septum is placed above the vertical channel of the base unit.

4 A preferred embodiment of the present invention also provides an alternative
5 structure to a septum which has a number of advantages. Instead of utilizing a septum to
6 seal a chamber, the present invention uses paired members. One member is typically on
7 a base assembly having a fluid channel while the other is on a joint pivoting with
8 respect to the base assembly. At least one of the paired members is compressible when
9 the pivoting member is rotated into a position which allows the noncompressible and
10 the compressible members to join. The paired members join to form a fluid sealing
11 joint. A fluid channel in a fluid connector (a fluid connector bearing one of the member
12 pairs) is joined to a fluid channel in the base (the base including the second of the paired
13 members). At least one resilient member, either on the pivoting member or on the base
14 assembly, contacts the other member (in fluid sealing relation) as pivoting action brings
15 the channel in the fluid connector into fluid communication with a cannula mounted on
16 the base assembly. These paired members may take a number of configurations as set
17 forth in more detail below, but typically are incorporated into the novel stationary
18 base/pivoting fluid connector combination to allow for a simple and effective
19 compressive seal between a fluid connector and a cannula bearing base.

20

21 BRIEF DESCRIPTION OF THE DRAWINGS

1 Fig. 1A is a front elevational view of infusion assembly of the present invention
2 showing the base assembly including the septum and the fluid connector engaged
3 therewith. The fluid connector is positioned with respect to the base assembly in an
4 “up,” “non-operative,” or “nonuse” position.

5 Fig. 1B is a side elevational cutaway view of the infusion assembly of Fig. 1
6 with fluid connector engaged to the base assembly.

7 Fig. 1C is a partial cutaway elevational view of base unit and septum of the
8 present invention illustrating the septum joined to the base unit and the septum body
9 having a vertical channel axially aligned with the vertical axis of the base unit cannula.
10 A horizontal channel perpendicular to the vertical channel is also illustrated.

11 Fig. 1D is a top elevational view of the infusion assembly of the present
12 invention illustrated in Fig. 1A.

13 Fig. 2A is a front elevational view of the infusion assembly of the present
14 invention with the fluid connector in a “down”, “operational,” or “use” position.

15 Fig. 2B is a side elevational cutaway view of Fig. 2A illustrating the manner in
16 which the fluid channel of the fluid connector axially aligns with the horizontal channel
17 of the septum/base assembly when in a down or use position. Fig. 2B also illustrates
18 the hinge member urged or depressed downwardly.

19 Fig. 2C is a partial cutaway view of the septum body showing vertical and
20 horizontal fluid channels therein. The fluid connector is in the down or use position (as
21 illustrated in Figs. 2A and 2B) further illustrating the manner in which a base wall of
22 the fluid connector may snugly engage a vertical wall of the septum so as to align the

1 horizontal channel of the septum with the fluid channel of the fluid connector and
2 provide a fluid flow path through the fluid channel of the fluid connector into the
3 cannula of the base assembly.

4 Fig. 2D is a top elevational view of the fluid connector engaged with the base
5 assembly and the fluid connector in the down or use position.

6 Fig. 2E is an alternate preferred embodiment of the present invention, wherein
7 the base unit includes the vertical and horizontal channels and a piercable septum is
8 located atop the vertical channel of the base assembly.

9 Fig. 3A is a side elevational cutaway view of the base and the septum of the
10 present invention without the fluid connector but with an insertion needle assembly in
11 place.

12 Fig. 3B is a front elevation view of Fig. 3A.

13 Fig. 3C is a partial front sectional view of the insertion needle in place
14 penetrating the septum and aligned with and partially within the cannula to allow for
15 placing the base assembly of the infusion assembly on a patient.

16 Fig. 3D is a top elevation view of the representations set forth in Figs. 3A and
17 3B.

18 Fig. 4A is a perspective view showing the under surface of a base of an alternate
19 preferred embodiment of the present invention, the base illustrated in Figs. 4A-4F for
20 use with
21 the fluid connector illustrated in Figs. 6A-6F.

1 Fig. 4B is a top elevational view of a base of an alternate preferred embodiment
2 of the present invention.

3 Fig. 4C is a cutaway side elevational view of a base of an alternate preferred
4 embodiment of the present invention of the section illustrated in Fig. 4D.

5 Fig. 4D is a bottom elevational view of a base of an alternate preferred
6 embodiment of the present invention.

7 Fig. 4E is a rear elevational view of a base of an alternate preferred embodiment
8 of the present invention.

13 fluid connector to the base assembly of the present invention.

14

15 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

16 As illustrated in the attached Figures, infusion system 10 is provided to deliver a
17 fluid, typically carried through a fluid delivery tube 18 into the body of a patient
18 typically through a cannula 12B.

19 The infusion system or assembly has been reduced to a minimum number of
20 pieces. This simplifies construction, assembly and use of the device. In one
21 embodiment of the invention three fundamental and basic pieces typically are separately
22 manufactured to construct the infusion assembly and include: base unit 12; septum

1 assembly 14; and fluid connector 16. The base and septum form the infusion body
2 assembly 13. In use on the patient, the assembly thus consists of two removably
3 assembled pieces – body assembly 13 (from base 12 and septum assembly 14) and fluid
4 connector assembly 16. In another embodiment discussed below the septum is
5 eliminated by using mating, complementary sealing members.

6 One function of the base unit 12 in systems having a septum is to provide
7 support for the septum and the fluid connector and to position them with respect to each
8 other so they may pivotally engage one another in a manner set forth below. The base
9 assembly also includes a cannula 12B which is capable of receiving an insertion needle
10 (see Figs. 3A-3D) for emplacement of the base assembly adjacent the skin with the
11 cannula depending downward through and beneath the skin, for delivery of fluid from a
12 remote reservoir through the fluid connector, septum and the cannula of the base and
13 into the patient.

14 To accomplish these and other functions, the base unit is seen to include a
15 generally planar, flat bottom surface 12A for resting directly against the skin of a
16 patient or against a double-sided adhesive pad 20 (see Fig. 1A) for removably attaching
17 the assembly indirectly to the skin of a patient.

18 With reference to Figs. 1A-2D, it is seen that above the bottom surface of the
19 base 12 are walls 14W defining a septum seat 12I on which a septum assembly 14 may
20 rest as set forth in more detail below. A portion of the base, typically defining a
21 depression therein, includes a cannula seat 12J dimensioned to receive an annular lip
22 12L of a cannula. A cannula 12B of soft rubber or plastic depends downward

1 perpendicular to the flat bottom surface 12A of the base. The cannula may be sonic
2 welded into the separately molded base prior to assembly of the product.

3 As set forth in Fig. 1B, the base 12 also includes a shoulder 12C which serves as
4 a first hinge section. The shoulder comprises a horizontal arm designed for engagement
5 of the fluid connector as seen in more detail below. Adjacent the shoulder are a pair of
6 spaced apart vertical opposed sidewalls 12D (one of the pair shown in Fig. 1B). These
7 sidewalls 12D, also serving as a portion of the first hinge section, are designed to
8 engage corresponding sidewalls of the fluid connector when lip 16C is engaged with the
9 shoulder 12C to hingedly and pivotally guide the fluid connector on to the septum
10 assembly, the septum assembly having been mounted to the base in the assembly
11 process.

12 The base may include a protector assembly having an orifice blocking leg 12E,
13 the leg being an extended member having a foot portion 12F at the removed end
14 thereof. The foot portion 12F extends generally perpendicularly from the longitudinal
15 axis of the leg. The leg is attached at a near end 12G by an integral (living) hinge, to
16 the base 12. In the manufacture of the base blocking, leg 12E is biased so that foot
17 portion 12F is elevated above the bottom surface of the base as illustrated in Fig. 1B
18 and 1C, for example. The base is manufactured from a material, such as plastic, that
19 has some resiliency and is molded with the leg in the “up,” “blocking,” or occluding
20 position as illustrated in Figs. 1B and 1C. The leg is attached at its near end 12G in a
21 manner such that it pivots downwardly easily about the near end from its normally
22 upwardly biased position. Thus, near end 12G acts as a “living hinge” incorporated into

1 the leg and base. Base 12 may also have a pair of fluid connector arm engaging
2 members 12H and 12 H' (see Fig. 1D), to resiliently engage arms 16I and 16I' of the
3 fluid connector to hold the fluid connector in a down or delivery position.

4 As seen in Fig. 1C, a septum assembly 14 has a septum body 14A, having a
5 hardness of a first durometer reading. The septum assembly typically includes a top
6 surface 14B, sidewalls 14C and a bottom surface 14D. In a preferred embodiment the
7 septum assembly 14 includes a fluid flow channel therein. A horizontal, first channel
8 leg 14E has an open first end 14F and an open second end 14G. The second end 14G
9 opens to a vertically aligned second channel leg 14H. The second channel leg 14H has
10 a first end 14I leading to the cannula and a second end 14M leading to a second end
11 14G of the first channel leg 14F. As noted with respect to Fig. 1C, septum assembly 14
12 may be glued or otherwise secured to septum seat 12I. The septum assembly may be a
13 single durometer sufficient for the insertion needle to penetrate or it may have two areas
14 of differing durometers at least one part of the top surface thereof being of a durometer
15 penetratable by an insertion needle.

16 For example, a soft septum member 14J may be incorporated into the septum
17 assembly through the use of a "two shot" molding method and likewise, there may be a
18 sidewall portion 14K which is of a softer durometer than the remainder of the septum
19 body. In such an embodiment a portion of the septum member is positioned above the
20 first channel 14E. It is to be pointed out, however, that the septum is typically shot as a
21 single unit – not two units separately manufactured and then glued or welded together,
22 as is known in the prior art. It is typically a single piece septum assembly which may

1 have areas of softer durometer, for example, so as to provide easier receipt of the
2 insertion needle in puncturing the top surface 14B. Sidewall port 14K may be,
3 preferably, ring shaped encircling as it is the port opening provided in septum body 14A
4 by open first end 14F of first channel 14E.

5 First channel leg 14E and second channel leg 14H are generally perpendicular to
6 one another, the first channel leg is typically horizontal and the second channel leg
7 typically vertical. When the fluid connector is in a down position, it is able to deliver
8 fluid to the septum assembly fluid channel via first end 14F of first channel leg 14E,
9 through the septum assembly 14 until the fluid reaches the second end 14G of first
10 channel leg. The fluid is then delivered to the second channel leg 14H, where it flows
11 downward under the impetus of gravity (or a feed pump, not shown) into the cannula
12 for delivery into the body of the patient.

13 A fluid connector 16 is provided for engagement with the base 12 of the body
14 assembly 13 in a rotatable fashion and is pivotable on the base for alignment with the
15 septum assembly to deliver fluid from the fluid delivery tube 18 to the fluid flow
16 channel of the septum assembly when the fluid connector has been rotated to a down or
17 operational delivery position (see Figs. 2B and 2C).

18 To accomplish this and other objects, fluid connector 16 is seen to have a near
19 end 16A, a body 16J, and a nose 16K projecting from the body (see Figs. 1A, 1B, 1D
20 and 2D). Opposite near end (16A) is a removed end (16B). The fluid connector has a
21 longitudinal axis 16Z. Removed end 16B includes a lip 16C which serves as a portion
22 of a second hinge section. The lip is designed for pivotal engagement with shoulder

1 12C of base 12. The fluid connector includes a pair of spaced apart sidewalls (16E)(see
2 Fig. 2D) which also serve as a part of the second hinge section and engage flush
3 adjacent the spaced apart sidewalls (12D)(see Figs. 1 and 1B) of the base. Thus, a
4 mechanism is provided for the fluid connector to easily and removably engage the base
5 at the shoulder while providing paired adjacent sidewalls to guide the fluid connector
6 from an up or non-delivery position (Figs. 1 through 1D) to a delivery or down position
7 (Figs. 2 through 2D).

8 Fluid connector 16 also includes a bottom surface 16D. The bottom surface
9 includes at least a portion thereof dimensioned to interfere with foot 12F of leg 12E as
10 the fluid connector moves towards the down position to urge the foot away from first
11 end 14F of fluid flow channel 14E. Figs. 1C, 2C, 1A and 2A illustrate the manner in
12 which the fluid connector in an up position does not interfere with the position of the
13 foot adjacent the first end of the first channel. In this “up” position the foot blocks the
14 channel and prevents the accumulation of harmful material at the first channel. When
15 the fluid connector is in a down position, it is seen that a portion of the bottom surface
16 16D has interfered with the foot of the leg to urge it to a down position positioning the
17 fluid delivery tube of the fluid connector adjacent the first channel to allow the passage
18 of fluid therethrough.

19 The bottom surface of the fluid connector may include recessed area 16H (see
20 Fig. 1A) that is contoured to snugly enclose the sidewalls and the top surface of the
21 septum assembly when the fluid connector is in a down position. The snug fluid sealing
22 relationship between raised walls 16G of the fluid connector and the septum assembly

1 may be appreciated, for example, with reference to Fig. 2C. Further, raised walls 16G
2 are seen to define a slightly convex surface which may encircle open end 16F' of fluid
3 delivery channel 16F. This is best seen in Fig. 2C. Raising the walls in this fashion,
4 along with providing septum assembly 14 with a raised ring shaped sidewall port 14K
5 provides a fluid tight seating arrangement between the fluid connector and the septum
6 such that fluid flowing from open end 16F' into first channel leg 14E will not leak out.
7 Some resiliency in sidewall port 14K is, therefore, desirable. Note that the bottom
8 surface of the fluid connector is dimensioned to allow interference with foot portion
9 12F of leg 12E while the fluid connector is urged into the closed position.

10 Fig. 2E illustrates an alternative base 12 and septum assembly 14 arrangement in
11 which the base 12 has molded therein a vertical and horizontal channel. A septum
12 member 14J, made of a durometer soft enough for an insertion needed to be emplaced,
13 sits atop the vertical channel leg, which is aligned with the lumen of the cannula. The
14 base and the fluid connector still pivotally engage. The fluid connector moves from a
15 delivery position where the fluid channel and the fluid connector is aligned with the
16 horizontal channel of the base to a non-delivery position wherein the two channels are
17 out of alignment. Other features noted in this alternative embodiment of Fig. 2E is the
18 absence of a living hinge (though one may be provided). Further, it can be seen that a
19 cannula retainer plate 15 may be used to improve the sealing of the cannula against the
20 base.

21 Figs. 3A through 3D illustrate an infusion set without the fluid connector but
22 with the insertion needle assembly 22 engaged therewith. More specifically, insertion

1 needle assembly 22 includes a handle 22A and a needle 22B. The needle is inserted
2 through a top portion of the septum vertically downward through the second channel
3 and the cannula until the removed end of the needle sticks out just past the removed end
4 of the cannula (see Fig. 3B). It is in this configuration that one gently inserts the
5 needle/cannula into a patient so that the cannula will depend downward underneath the
6 skin such that the base or the adhesive member 20 will lay adjacent the skin. The handle
7 may then be removed and discarded. The fluid connector 16 may be attached in an up
8 position for pivoting downward and commencing delivery of fluid to the patient.

9 Figs. 4A through 4F illustrate a base 112 of yet another embodiment of the
10 present invention, illustrating an alternate manner of pivotally holding or engaging the
11 fluid connector to the body.

12 As seen in Figs. 4A-4F, arm engaging members 112H and 112H' project
13 vertically from and integral with base 112 which will resiliently engage arms 116I and
14 116I' (see Fig. 6B) of the fluid connector in a manner that will enclose the arm engaging
15 members when the fluid connector is in a down or use position.

16 It may also be appreciated with reference to these illustrations that the novel
17 septum 114 shows a raised nose 144F (Figs. 5A and 5B). It may be appreciated that the
18 raised nose will help insure a good fit to the fluid connector when the fluid connection
19 is in a down position to help insure the integrity of the septum/fluid connection
20 interface. Septum 114 is also seen to be a single piece, single shot device. As seen in
21 Fig. 4B and 4C, base 112 may include resilient septum engaging bosses or tabs 113J

1 (here three) for resiliently holding and positioning the septum engaged with the base, by
2 engagement with similarly dimensioned notches 114G (see Fig. 5A) in the septum.

3 Figs. 4A through 4F illustrate details of the alternative base 112. Fig. 4C shows
4 that the base features a downward depending cannula 112B. The cannula depends
5 from a flat bottom surface 112A. Optionally, a stepped portion 113A of the bottom
6 may include a needle guard lip 113B. Septum housing 112J is designed to receive
7 septum 114 (see Fig. 5A) therein and may do so via the engagement of tabs 113J with
8 notches 114G in the resilient septum. Lip portion 112C includes hook sidewalls 112D.
9 Hook portion and hook sidewalls 112D are designed to engage cross-arm 116C of fluid
10 connector 116 (see Fig. 6C). Hook sidewalls 112D will engage sidewalls 117C
11 adjacent cross-arm 116C so as to maintain a uniform guided motion between the open
12 and the closed position of the fluid connector. Thus, hook sidewalls 112D and
13 sidewalls 117C adjacent cross-arm 116C and hook portion 112C engaging cross-arm
14 116C will function, when engaged, to secure the fluid connector to the base when the
15 fluid connector is in up position and to guide the fluid connector between the up or open
16 position in a closed or down position. The fluid connector will be engaged when in a
17 down position by engagement between the arm engaging members of the base and the
18 arms of the fluid connector as well as engagement at the hook and sidewalls.
19 Engagement of recessed area 116H of fluid connector 116 (see Fig. 6B) with the septum
20 and the septum seat will occur when the fluid connector is in the down position. Leg
21 112E is seen to have a living hinge and a foot 112F and to function, pivoting with
22 engagement with the fluid connector, in a manner set forth with earlier embodiments.

1 Arm engaging members 112H and 112H' of base 112 are seen to include lip
2 portion 113H and 113H' such that when the fluid connector is urged to a down position
3 the lip portion may engage corresponding notches 116Z (see Fig. 6B), in the inside
4 sidewalls of the arms 116I and 116I' of the fluid connector to hold the fluid connector in
5 a down position. The sidewalls of the arm engaging members may be canted so that
6 they may engaged in an interfering manner with walls of the fluid connector to urge the
7 fluid connector as it is pushed to a down position towards and against the septum for a
8 good seal.

9 Figs. 5A through 5C illustrate a resilient septum 114 of the infusion system.
10 The septum includes notches 114G which will engage the tabs 113J of the septum seat
11 of the base when the septum 112 is pressed into the seat. Typically, septum 114 also
12 includes a flat top surface 114T for flush engagement with the fluid connector when the
13 fluid connector is in a down position. Bottom surface 114B typically lays flush against
14 the base. In Fig. 5C it is seen that there is a first channel leg 114C with an open end
15 114C' that is typically parallel to the base and joins a second channel leg 114D with
16 open end 114D', which open end is typically located over the top end of the cannula
17 112B when the septum is in place on the base.

18 Figs. 6A through 6F illustrate a cooperating fluid connector 116 for use with
19 base 112. A smooth top 116T and a pair of resilient arms 116I and 116I' extending
20 forward from the rear portion of the fluid connector are shown. Notches 116Z are on
21 the inner faces of arms 116I and 116I'. The arms define slots 116S between the two
22 outboard arms and the centrally located nose 116K. There is some flexibility in the

1 arms allowing them to be squeezed inward for release of the fluid connector from a
2 down position in which the arms are engaged with the arm engaging members of the
3 base. Ribs 116X on the outer surface of the arms provide for finger engagement with
4 the fluid connector arms for ease of moving the fluid connector between a raised and
5 lowered position and for urging the arms inward for release of the fluid connector from
6 the down position.

7 Fluid connector 116 has a near end 116A and a removed end 116B. Sidewalls
8 117C are located at removed end 116B. Cross-arm 116C which is designed to
9 removably and snugly engage lip portion 112C of the base. The hook portion
10 sidewalls snugly and slidably engage sidewalls 117C of the fluid connector as the fluid
11 connector is moved between a raised and lowered position. On the underside of the
12 fluid connector there is seen a recessed area 116H dimensioned for receipt of the
13 septum and the septum seat. When the fluid connector moves to a down position there
14 is a wall 116Y (see Fig. 6B) that is located so that it interferes with, by contact, the foot
15 portion 112E of leg portion 112F of leg 112E to urge it away from its up or raised
16 position adjacent the nose of the septum to a down position away from the nose of the
17 septum. In the down position open end 116F' of fluid delivery channel 116F snugly
18 sits adjacent open end 114C' of the septum so fluid may flow through the septum and
19 through the cannula into the patient.

20 Fig. 7 illustrates the manner in which base 112 as illustrated in Figs. 4A-4F
21 engages fluid connector 116. The manner of engagement provides hinged movement
22 between the base and the fluid connector. The illustration in Fig. 7 shows hook portion

1 112C in the base and the manner in which it engages with the fluid connector. The
2 manner of connection is “hinged” allowing the fluid connector to move from a non-use
3 position by rotation downward to a use position. In the use position a fluid channel in
4 the fluid connector will connect with a fluid channel in the base to provide fluid to the
5 cannula and to the patient.

6 Figs. 8A-8B illustrate the needle hub assembly 122. The assembly has a handle
7 112A and a needle 112B projecting perpendicularly therefrom. The fluid connector is
8 apart from the body of the base when the needle hub assembly engages septum, base
9 and cannula. After the unit is in place upon the user the needle hub assembly may be
10 withdrawn and discarded, and the fluid connector, with the fluid connector line
11 attached, may be engaged to the back and moved from an up position to a lower or use
12 position for providing fluid to the patient from a remote reservoir (not shown). The
13 removed end of the needle assembly includes the hollow portion 112X with the window
14 112Y cut out therefrom, the hollow portion and window shaped to fit around septum
15 housing 112J of base when the septum is engaged therewith. Interference between the
16 sidewalls of the hollow portion and the window with the septum and the sidewalls of
17 the septum housing may provide a guide to center the needle so that it is properly
18 aligned with the cannula.

19 One preferred embodiment of the present invention for a “septumless” infusion
20 system is illustrated in Figs. 9 through 36. Figs 9 and 10 illustrate an alternate preferred
21 embodiment of an infusion assembly 200, the infusion assembly having a base 212, a
22 first sealing member 214, a fluid connector 216 and a fluid delivery tube 218. An

1 insertion needle assembly 220 (see Fig. 10) may be provided for implantation of the
2 infusion assembly on to a patient.

3 Fig. 10 shows insertion needle assembly 220, the insertion needle assembly
4 including a handle 228 having a needle 228A projecting thereto. A foot 228B may help
5 locate the needle assembly by engagement with cutout portion 212C of the base.

6 Infusion assembly 200 is seen to be "septumless." It is seen to include a
7 pivoting fluid connector 216 for engagement with a base 212, the fluid connector being
8 rotatable between a use (delivery) and a non-use (non-delivery) position. The base 212
9 has a flat bottom portion 212A. A soft and flexible cannula 212B is provided and
10 defines a lumen therein. Cannula 212B extends vertically downward from the flat
11 bottom portion of the base.

12 The base may include walls defining a cutout portion 212C which serves as a
13 hinge section. The cutout is shaped for receipt of a hinge section of the fluid connector
14 as set forth in more detail below. The cutout includes vertical paired sidewalls 212D
15 which will engage and guide the fluid connector (when hingedly engaged with the base)
16 from a non-delivery (or "up") position to a delivery position (or "down" position) as set
17 forth below. The base may include vertically projecting alignment bosses 212E for
18 engagement with the fluid connector to assist in guiding the fluid connector to a down
19 or delivery position. The base may also include vertically upstanding legs 212F and
20 212G (Fig. 21) for releasable engagement with the arms of the fluid connector to hold
21 the fluid connector in a down or use position. In an alternate preferred embodiment of
22 infusion assembly 212, a slide 213 may be used (see Figs. 21 through 28), the slide for

1 protectively covering a fluid channel 214D when the fluid connector is either removed
2 from the base or out of its “down” or delivery position as set forth in more detail below.

3 Turning to Fig. 18, the figures also illustrate a first sealing member 214 which
4 typically includes a body portion 214A and may include a resilient “O” ring 214B. The
5 first sealing member is typically at least partially resilient and may include a resilient
6 raised bead 214C (see Fig. 17). In any case, first sealing member 214 typically defines
7 a fluid channel 214D therein and is dimensioned for receipt into base 212 as seen in
8 Figs. 9 and 11. Thus, first sealing member may be integral with base 212. It can be
9 seen that fluid connector 216 includes a bottom wall 216A and has a fluid channel 216B
10 therethrough (see Fig. 9). Fluid channel 216B may include a first leg 216C and a
11 second leg 216D. Where fluid channel 216B meets bottom wall 216A, a port 216N is
12 defined which port will join, when the fluid connector is in a delivery position, the fluid
13 channel 214D of a first sealing member. The fluid connector typically includes an arm
14 or lip 216E projecting therefrom shaped to engage cutout 212C and sidewalls 212D of
15 base 212 in releasable fashion so that when the lip nests or seats snugly within the
16 cutout, the fluid connector may be rotated from an up position to a down position while
17 being guided onto bosses 212E (which bosses assist with the guidance and alignment of
18 the base with the fluid connector) (see Figs. 12-14), if used, and such that legs 216F and
19 216G having leg cutouts 216H and 216I will resiliently and releasably engage legs 212F
20 and 212G to releasably lock the fluid connector to a down position. In approaching the
21 full down position it will be noted that either “O” ring 214B or raised bead 214C will
22 engage the bottom wall 216A of the fluid connector in the area of port 216N in a

1 resilient manner so as to join in fluid sealing relation the port of the fluid connector to a
2 port in fluid communication with the lumen of cannula 212B so that fluid may be
3 delivered through the fluid connector into the body and into the cannula without
4 leaking.

5 Turning now to Figs. 21 through 29 (alternate embodiments of slide protector),
6 it may be seen that the base may include a protective member or slide 213. The slide is
7 capable of moving from an out of engagement (non-occluding) position to an
8 engagement (occluding) position, the occluding position protecting the fluid channel
9 214D from collecting debris or releasing liquid when the fluid connector is disengaged
10 from the base. It is seen that slide 213 may include a pair of oppositely mounted ears
11 213A and 213B, which ears may protrude from a tabular body 213C. The body may
12 include a vertically downwardly depending guide boss 213D with the guide boss having
13 extending from the bottom thereof a pair of guide legs 213E and 231F. Slide 213 is
14 designed for slidable engagement with the base 212 as seen in Figs. 21-23 and 27-28.
15 More specifically, it is seen that the base may include cam slots 212J and 212K which
16 cam slots may be adjacent to slider channel 212L. Slider channel 212L may be
17 dimensioned for receipt of guide boss 213D therein such that horizontally projecting
18 guide legs 213E and 213F capture the base between the ears of the slide and the guide
19 legs of the slide so that the slide may move between an open or out of engagement
20 position as seen in Fig. 21 to a use or protected position as seen in Fig. 23K, which
21 position protects the base from receiving liquid or debris that may enter the fluid
22 channel therein.

1 Figs. 30 and 31 illustrate a preferred embodiment of slide or protective member
2 213. This embodiment includes only a pair of longitudinal extending guide ridges for
3 resilient engagement to the slots of the base so as to be slideable with the base.

4 A mechanism for moving the slide between the two positions is provided. When
5 the fluid connector is removed from the base, the slide should be in the protected
6 position placed there manually by the user. When the fluid connector is engaged to the
7 base and urged to the down position, it is seen that the use of a pair of novel cams 216J
8 and 216K (Fig. 23) for engagement with ears 213A and 213B of the slide and slots 212J
9 and 212K as the fluid connector moves towards the down position to urge the slide
10 towards the open position.

11 Figs. 27 through 29 illustrate another embodiment of a slide 213 which is also
12 capable of moving between an open (non-occluding) and a protected (occluded)
13 position and wherein the infusion device includes structure to move the slide from the
14 occluded position to the non-occluded position when the fluid connector is moved into
15 the down or delivery position. In this alternate embodiment of the infusion assembly
16 200, it is seen that a cam surface 216L on the fluid connector will interfere with the
17 shaped top surface 213Z of the slide illustrated in Fig. 28 so that the cam surface urges
18 the slide from a protected position to the open position when the pivoting fluid
19 connector is urged to the down position.

20 Turning now back to the "septumless" sealing means, it may be seen that the
21 pair of members, at least one of which is resilient, may take on a variety of
22 configurations. For example, it has been discussed above that a simple "O" ring in

1 conjunction with interference with a bottom surface of the fluid connector may
2 comprise a fluid sealing pair so as to encircle the joint between the channel of the fluid
3 connector and the channel of the seal or base, so as to join fluid flowing through the
4 fluid connector to the lumen of the cannula and then into the patient. Fig. 19 illustrates
5 a bead 214C on a hard plastic bottom surface of a fluid connector receiving flush
6 against an elastomeric seal adjacent a channel in the seal to join the channel of the fluid
7 connector to the cannula in fluid sealing in relation. Fig. 20 illustrates a circular
8 depression in a resilient sealing member for joining a similarly dimensioned cylindrical
9 projection having canted walls on the bottom surface of the fluid connector when the
10 fluid connector is snapped down into the use position. Again, the figures illustrate
11 paired members, at least one of which is resilient, to encircle the junction of a port in
12 the base to a port in the fluid connector. Fig. 29 illustrates an embodiment of the
13 invention wherein the bottom surface of the fluid connector includes a resilient or non-
14 resilient ridge 216X that includes port 216N. The base may be configured to be flat and
15 either compressible or non-compressible (only if the ridge is compressible) where it
16 meets ridge 216X when the fluid connector moves to the down or use position.

17 Figs. 32 through 35 illustrate a variety of ways in which the seal 214 may be
18 incorporated into base 212. Fig. 32 illustrates walls of the base dimensioned with a lip
19 for receipt of a notch bearing seal thereinto, followed by the receipt of a retaining plate
20 212W for capturing and integrating the seal into the base. Figs. 33 and 33A illustrate a
21 seal having resilient legs, the legs having a resilient head thereon, for receipt into bores
22 in the base. Fig. 34 illustrates a base with a cutout dimensioned for receipt of a pliable

1 or resilient projection of the seal thereinto. Fig. 35 illustrates a seal having an adhesive
2 219 applied thereto to join the seal permanently to the base to “capture” or sandwich a
3 lip on the cannula to the base. Indeed, Figs. 33 and 34 illustrate that the seal may be
4 used to engage an annular lip on the near end of the cannula to locate and integrate the
5 cannula into the base.

6 Fig. 36 illustrates yet another novel embodiment of the invention wherein the
7 base 212 may include a lip 212Y bearing extension for engaging a lip 216Y defining a
8 removed end of the fluid connector 216. Further, Fig. 36 illustrates an advantage of the
9 pivoting, “septumless” infusion assembly. Namely, it provides a fluid connector and
10 base wherein one end of the fluid connector is engaged to the base and the other end is
11 dimensioned for receipt of a small force, rotating the fluid connector to a down position,
12 and wherein the fluid connector is designed to releasably and compressibly engage the
13 seal between the pivot end and the rotated end. Thus, a mechanical advantage is
14 applied wherein the resistant force, which must be overcome to create the compression
15 required for an effective seal is between the pivot arm and the small applied force.
16 Indeed, the sealing member in the preferred embodiment can be seen to be closer to the
17 articulation point between the base and the fluid connector in a preferred embodiment
18 illustrated in Fig. 36 closer than is when compared to the distance to the removed end of
19 the fluid connector, where the rotational force is typically applied in moving the fluid
20 connector between an up or non-use position to a down or used position.

21 Although the invention has been described with reference to a specific
22 embodiments, this description is not meant to be construed in a limiting sense. On the

1 contrary, various modifications of the disclosed embodiments will become apparent to
2 those skilled in the art upon reference to the description of the invention. It is therefore
3 contemplated that the appended claims will cover such modifications, alternatives, and
4 equivalents that fall within the true spirit and scope of the invention.

5

- 1 1. An infusion system for delivery of a fluid from a remote source into a patient's
2 body comprising:
3 a main fluid infusion unit having a cannula, said cannula attached at a near end
4 to an underside of said main fluid infusion unit, a first fluid channel in
5 fluid communication with said cannula, and a first hinge section;
6 a fluid connection line having a near end and a removed end, said fluid
7 connection line engagable at said removed end to said remote source;
8 and
9 a fluid connector assembly having a second fluid channel attachable to said near
10 end of said fluid connection line, and a second hinge section;
11 said first hinge section cooperating with said second hinge section to
12 allow pivotal movement of said system from a first non-delivery
13 position wherein said first fluid channel is not in fluid
14 communication with said second fluid channel to a second
15 delivery position wherein said first fluid channel is in fluid
16 communication with said second fluid channel to deliver said
17 fluid from said remote source through said cannula and into said
18 patient.
19
20 2. The system of claim 1 further comprising:

1 a main fluid infusion unit emplacement member having an insertion needle, said
2 insertion needle adapted to extend through said main fluid infusion unit and extend
3 beyond a distal end of said cannula when said system is in a first emplacement position.

4

5 3. The system of claim 1 further comprising a septum.

6

7 4. The system of claim 1 wherein said septum is a one shot fabrication.

8

9 5. The system of claim 1 further comprising a septum wherein at least a portion of
10 said septum is positioned above said first fluid channel in said main fluid infusion unit.

11

12 6. The system of claim 1 further comprising:

13 a first sealing surface surrounding a port opening in said first fluid channel of
14 said main fluid infusion unit; and

15 a second sealing surface surrounding a second port opening in said second fluid
16 channel of said fluid connector assembly.

17

18 7. The system of claim 6 wherein said first sealing surface further comprises a
19 compressible seal member, said compressible seal member cooperating with said
20 second sealing surface to form a seal-to-surface fluid seal connection when said system
21 is in said second delivery position.

22

1 8. The system of claim 6 wherein said second sealing surface further comprises a
2 compressible seal member, said compressible seal member cooperating with said first
3 sealing surface to form a seal-to-surface fluid seal connection when said system is in
4 said second delivery position.

5

6 9. The system of claim 1 further comprising:
7 a first fluid channel protector affixed to said main fluid infusion unit for
8 occluding a port opening in said first fluid channel, said protector movable from a first
9 occluding position to a second non-occluding position.

10

11 10. The system of claim 9 wherein said fluid connector assembly further comprises:
12 a protector engagement member, said protector engagement member urging said
13 first fluid channel protector from said first occluding to said second non-occluding
14 position as said fluid connector assembly is pivoted about said first and second hinge
15 sections.

16

17 11. The system of claim 9 wherein said main fluid infusion unit further comprises
18 slots cooperating with legs on said first fluid channel protector, said slots adapted to
19 guide said first fluid channel protector from said first occluding position to said second
20 non-occluding position.

21

22 12. The system of claim 6 further comprising:

1 a first fluid channel protector affixed to said main infusion unit for occluding a
2 port opening in said first fluid channel, said first fluid channel protector movable from a
3 first occluding position above said first sealing surface to a second non-occluding
4 position when said system is pivoted from said first non-delivery position to said second
5 delivery position.

6

7 13. The system of claim 1 wherein said second hinge section on said first end of
8 said fluid connector assembly is opposite a channel-to-connection line and on said fluid
9 connector assembly, said cooperating first and second hinge sections forming an
10 articulation point such that a closing force applied at said channel-to-connection line
11 and urges said system from said first non-delivery position to said second delivery
12 position.

13

14 14. The system of claim 10 wherein said protective member engagement member
15 includes a cam.

16

17 15. The system of claim 1 wherein said first hinge section includes walls defining a
18 cutout, and wherein said fluid connector assembly includes a projecting member
19 adapted for pivotal receipt into said cutout.

20

1 16. The system of claim 1 wherein said first hinge section includes walls defining a
2 hook and said second hinge section includes an arm for pivotal engagement with said
3 hook.

4

5 17. The system of claim 6 wherein said first sealing surface includes an "O" ring.

6

7 18. The system of claim 6 wherein said first sealing surface includes a raised bead.

8

9 19. The system of claim 6 wherein said second sealing surface includes a raised
10 member.

11

12 20. The system of claim 19 wherein said raised member is pliable and dimensioned
13 for compression seating with said first sealing member.

14

15 21. The system of claim 6 wherein one of said first or said second sealing surfaces
16 includes raised walls and the other of said first or said second sealing surfaces includes
17 walls defining a depression dimensioned for engagement with said raised walls.

18

19 22. The system of claim 1 wherein said fluid connector assembly and said main
20 infusion unit are dimensioned such that, when said fluid connector assembly is in said
21 second delivery position, at least part of said first channel is axially aligned with at least
22 part of said second fluid channel.

1

2 23. The system of claim 1 wherein said main fluid infusion unit includes notches
3 and said cannula includes a circular lip at a near end thereof, said notches dimensioned
4 for receipt of said lip therein.

5

6 24. The system of claim 23 wherein said first sealing surface engages said lip to
7 locate and retain said cannula integral with said main infusion unit.

8

9 25. The system of claim 1 further comprising means to releasably lock said fluid
10 connector assembly into said second delivery position.

11

12 26. The system of claim 9 further comprising means to releasably lock said fluid
13 connector assembly into said second delivery position.

14

15 27. The system of claim 25 wherein said means to releasably lock said fluid
16 connector assembly into said delivery position includes resilient arms on said fluid
17 connector assembly.

18

19 28. The system of claim 1 wherein said fluid connector assembly and said main
20 fluid infusion unit are adapted such that said fluid connector assembly is releasable
21 from said main infusion unit when in said non-delivery position.

22

1 29. The system of claim 1 wherein said fluid connector assembly and said main
2 fluid infusion unit are adapted to lockably engage one another in said delivery position,
3 said delivery position including when said fluid connector assembly is parallel to the
4 skin of said patient and near end of said fluid connection line engages said fluid
5 connector assembly parallel to said skin of said patient.

6

7 30. The system of claim 29 wherein said fluid connector assembly and said main
8 fluid infusion unit are adapted to move from said non-delivery position to said delivery
9 position, said non-delivery position locating said fluid connector assembly
10 approximately vertical with said main infusion unit.

11

12 31. The system of claim 25 wherein said fluid connector assembly is adapted to
13 release from said main infusion unit when in said non-delivery position.
